

# Solute Translational Diffusion in Ionic Liquids

Anne Kaintz & Mark Maroncelli,  
 Department of Chemistry,  
 The Pennsylvania State University

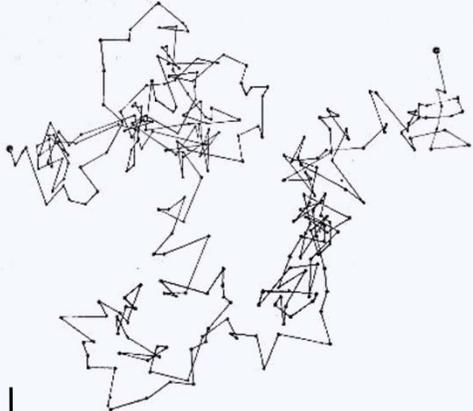

# Motion, Friction, & Hydrodynamic Models

Einstein Relation:

$$D = k_B T / \zeta$$

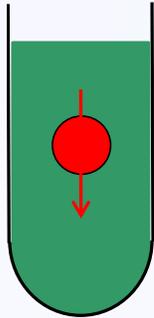

diffusion coefficient      friction constant

Stokes Law for Spherical Object:

$$\zeta_{sphere} = 6\pi\eta R$$

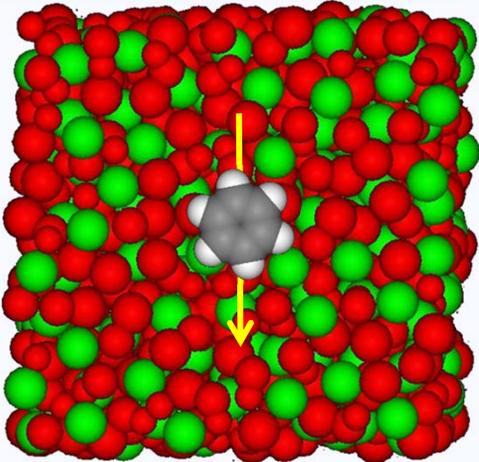

solvent viscosity      object radius

Stokes-Einstein-(Sutherland):

$$D_{SE} = \frac{k_B T}{6\pi\eta R}$$

- 6π for stick, 4π for slip boundary conditions
- shape is a minor effect

Rotational Equivalent:

$$D_{SED} = \frac{k_B T}{6\eta V}$$

- 6 for stick, 0 for slip BCs
- shape is critical
- observable more complex

are hydrodynamic models useful?

# Terminology & Perspective

**Self Diffusion:** diffusion of a molecule in its own liquid

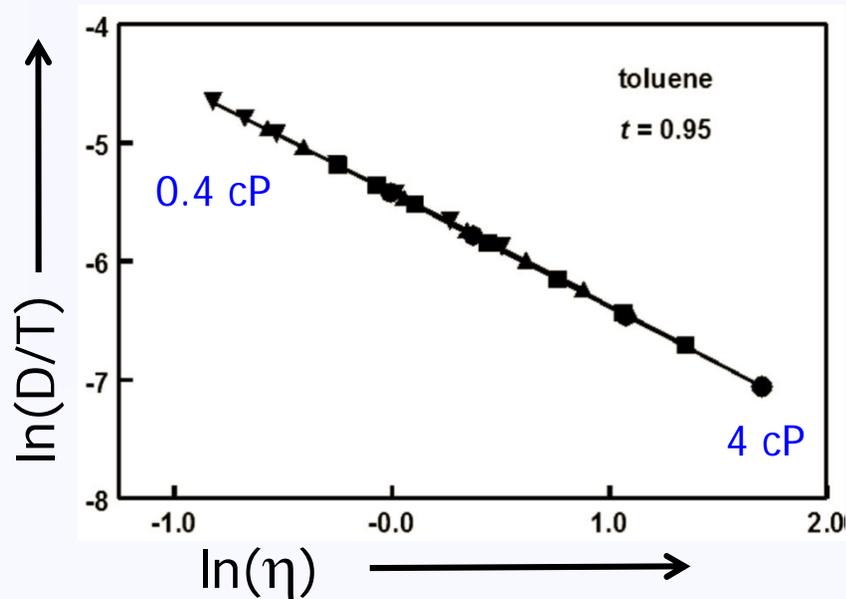

**Tracer Diffusion:** diffusion of an infinitely dilute solute in a solvent

**Empirical Focus:** 
$$\frac{\zeta_{obs}}{\zeta_{SE}} = \frac{D_{SE}}{D_{obs}}$$

# Self-Diffusion: Viscosity Scaling

## D/T vs $\eta$ - Toluene

- in most liquids T or P variation of  $\eta$  leads to near hydrodynamic behavior:

$$D/T = A\eta^{-p} \text{ with } p \cong 1$$

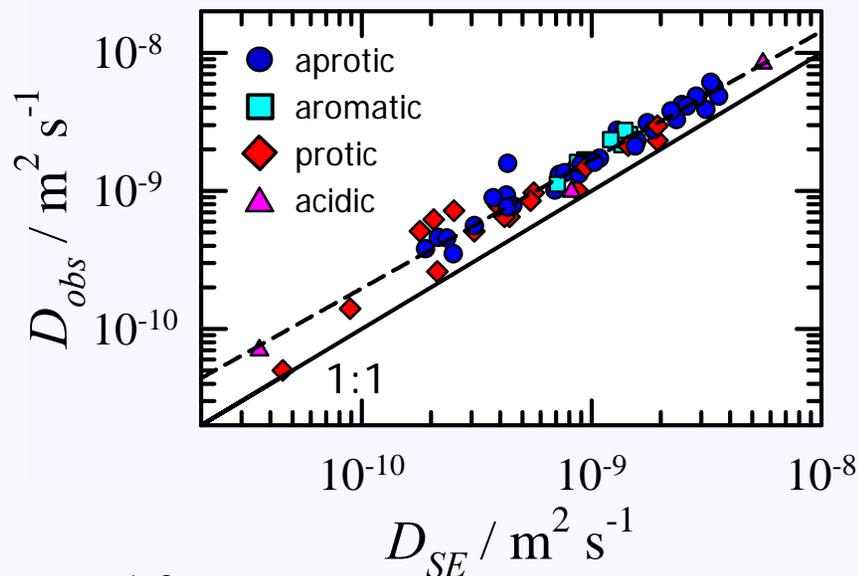

## Exponent $p$ in a Variety of Liquids

# Self-Diffusion: Conventional Liquids

## D in 64 Common Solvents

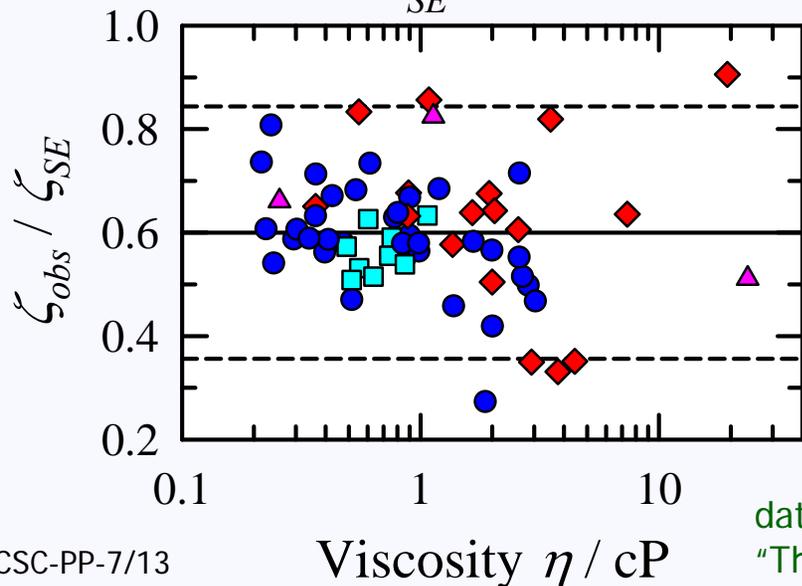

How accurate are SE predictions?

$$D_{SE} = \frac{k_B T}{6\pi\eta R_U}$$

assume solute (=solvent) radius related to vdW volume:

$$R_U = (4V_U / 3\pi)^{1/3}$$

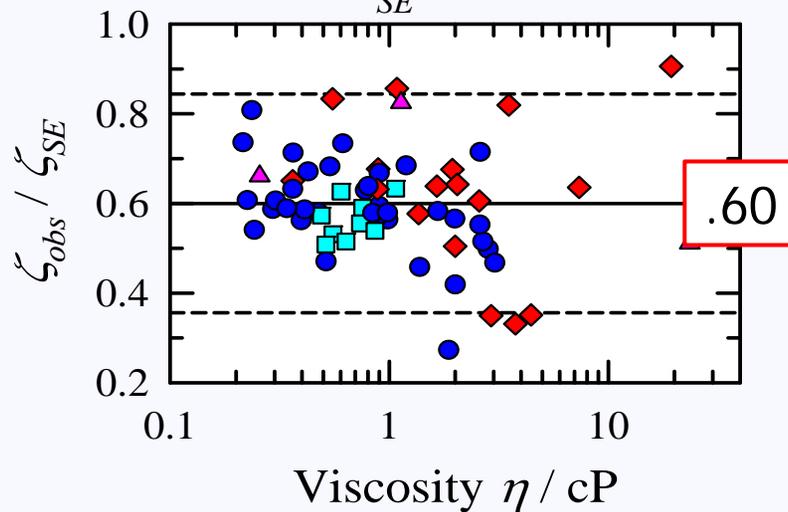

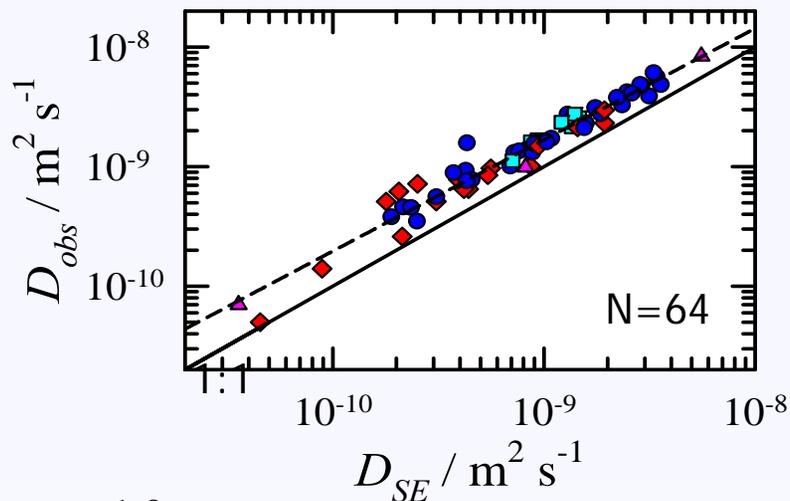

$$\frac{\zeta_{obs}}{\zeta_{SE}} = .60 \pm .24_{(2\sigma)}$$

➤ SE is remarkably accurate (average w. slip BC is ~1) !

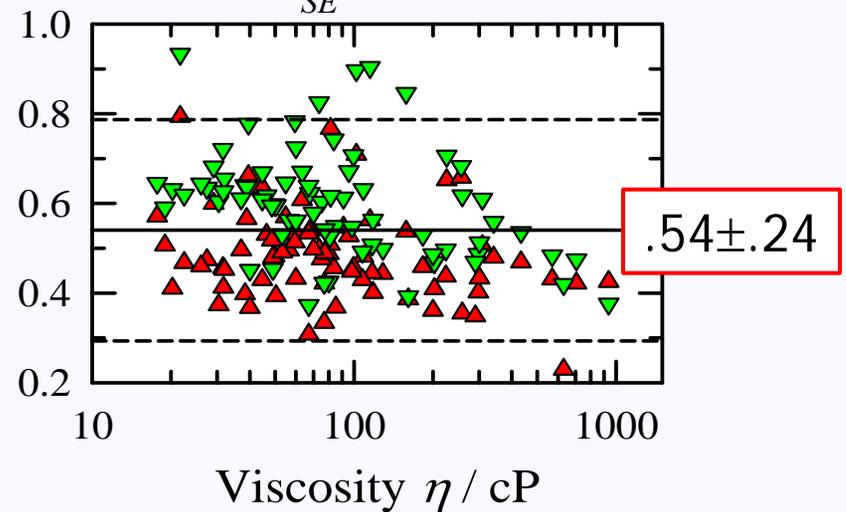

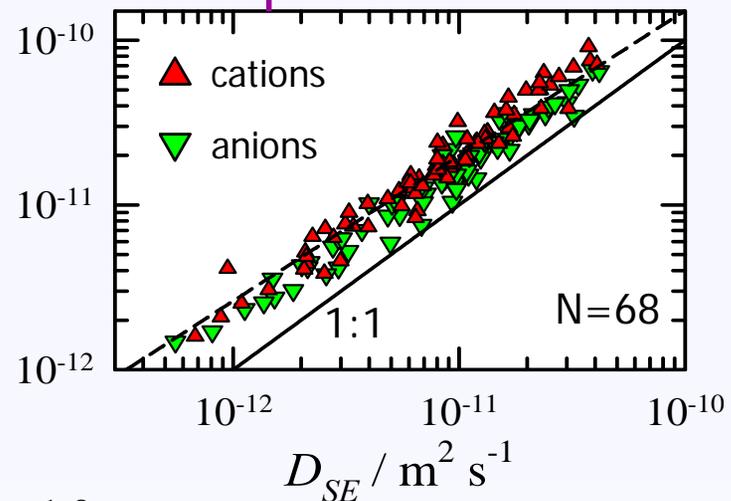

data from Y. Marcus,  
"The Properties of Solvents" (1998)

# Similar Accuracy in Ionic Liquids

## Conventional Solvents

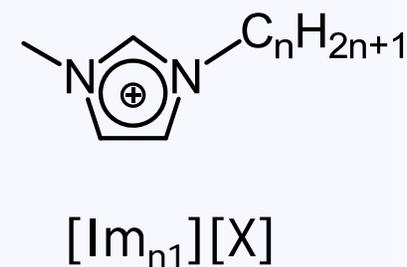

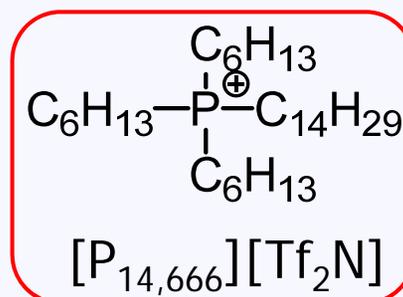

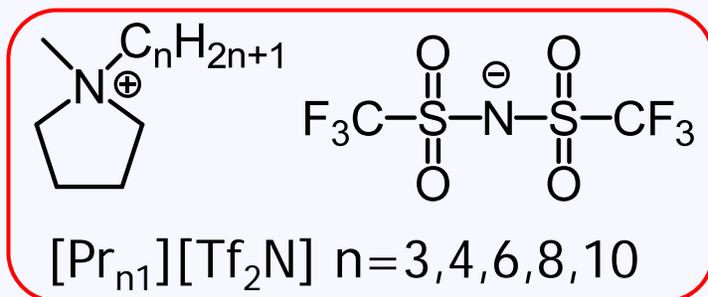

## Ionic Liquids

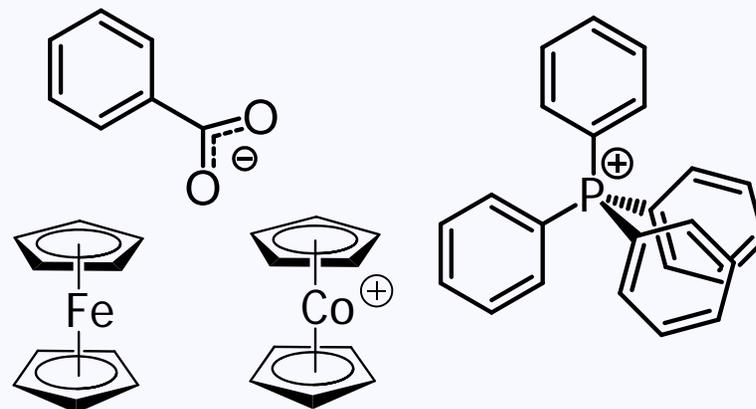

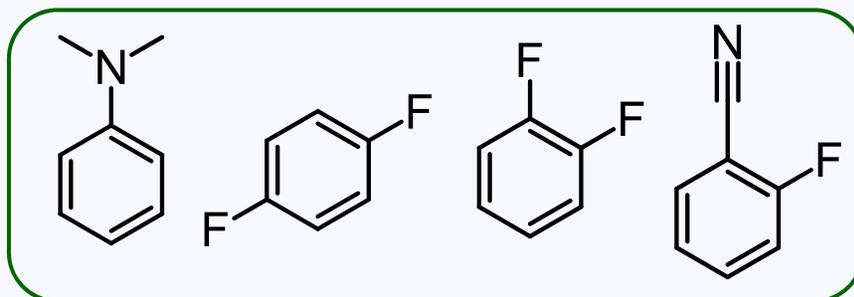

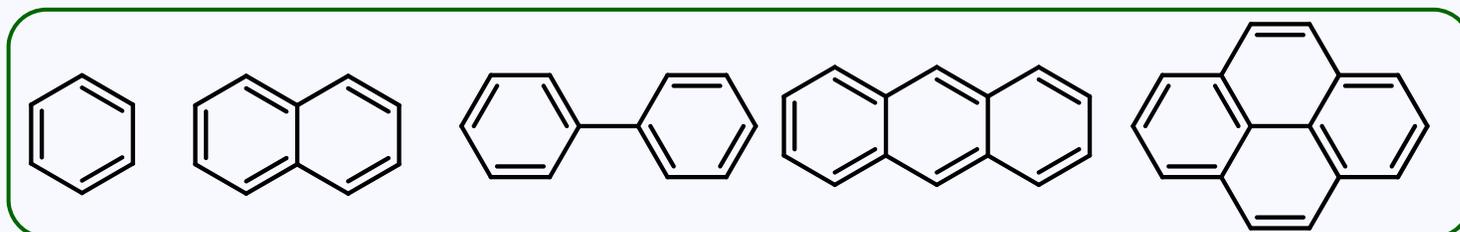

# Our Work: Solute Diffusion in ILs

- PFG-NMR measurements of solute D at near infinite dilution

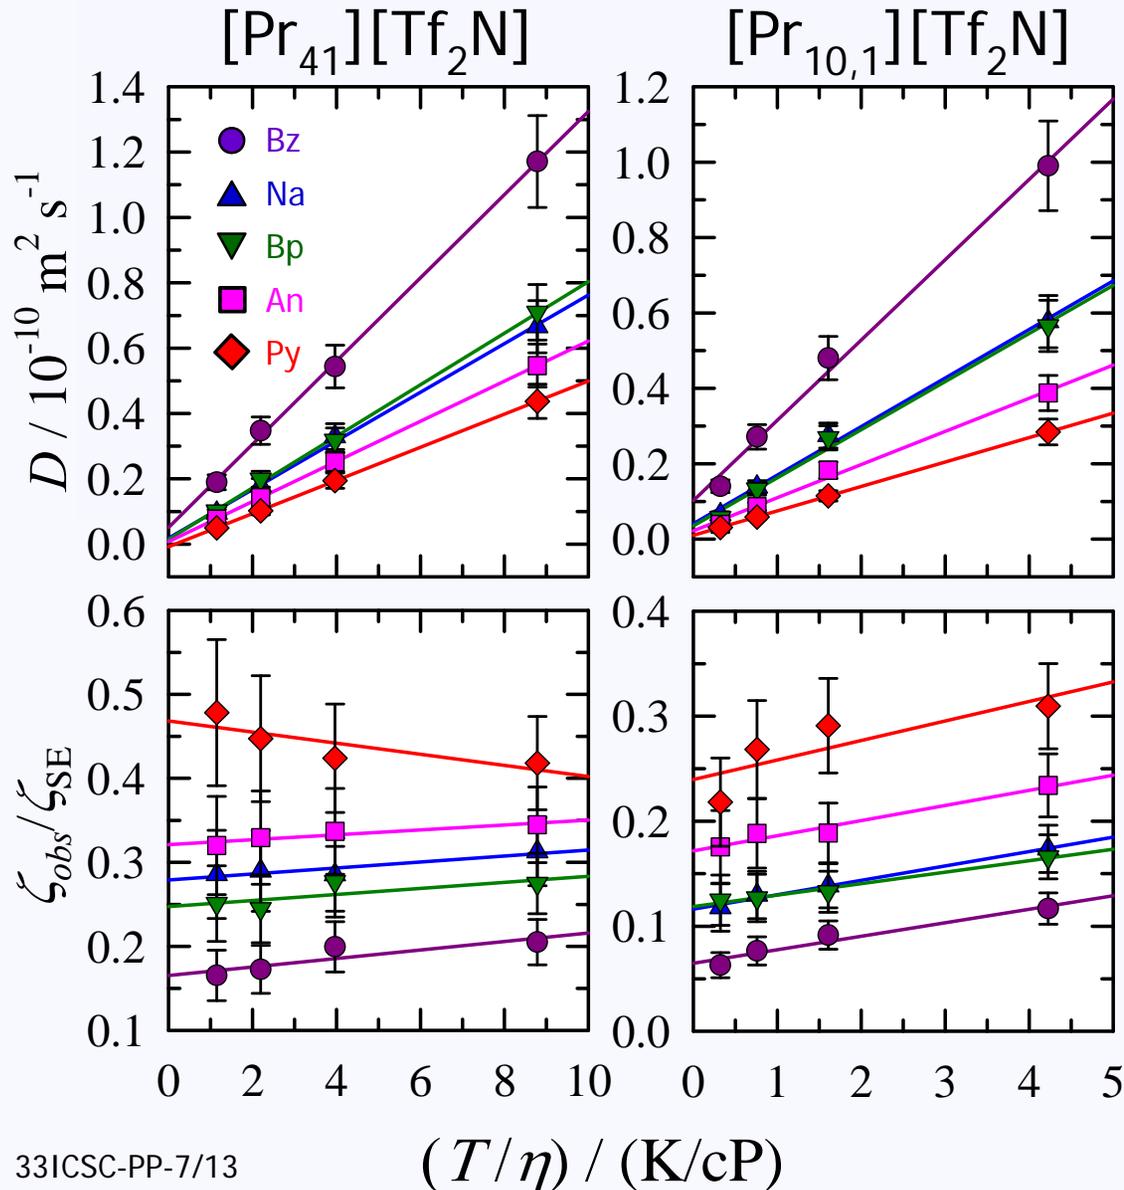

Ionic Liquids

Solutes

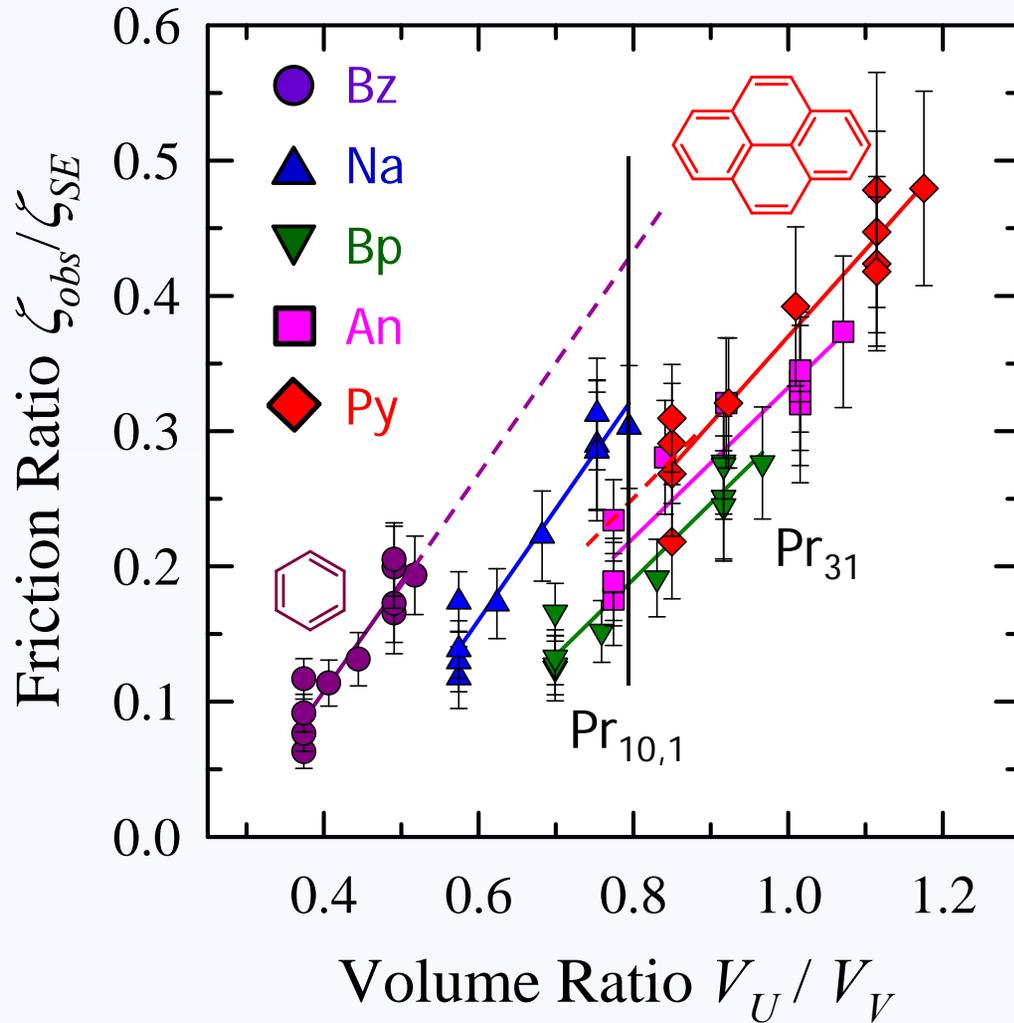

# Temperature Dependence

- for a single solute-solvent pair  $D$  is nearly  $\propto T/\eta$
- fit to  $\propto \eta^{-p}$  with  $p \sim 0.9$
- $\zeta \uparrow$  with solute  $\uparrow$  size but not as fast as  $R_U$
- $\zeta_{\text{obs}}/\zeta_{\text{SE}} \downarrow$  with  $\uparrow$  cation size

# Size Dependence

## Aromatics in [Prn<sub>1</sub>][Tf<sub>2</sub>N] Series

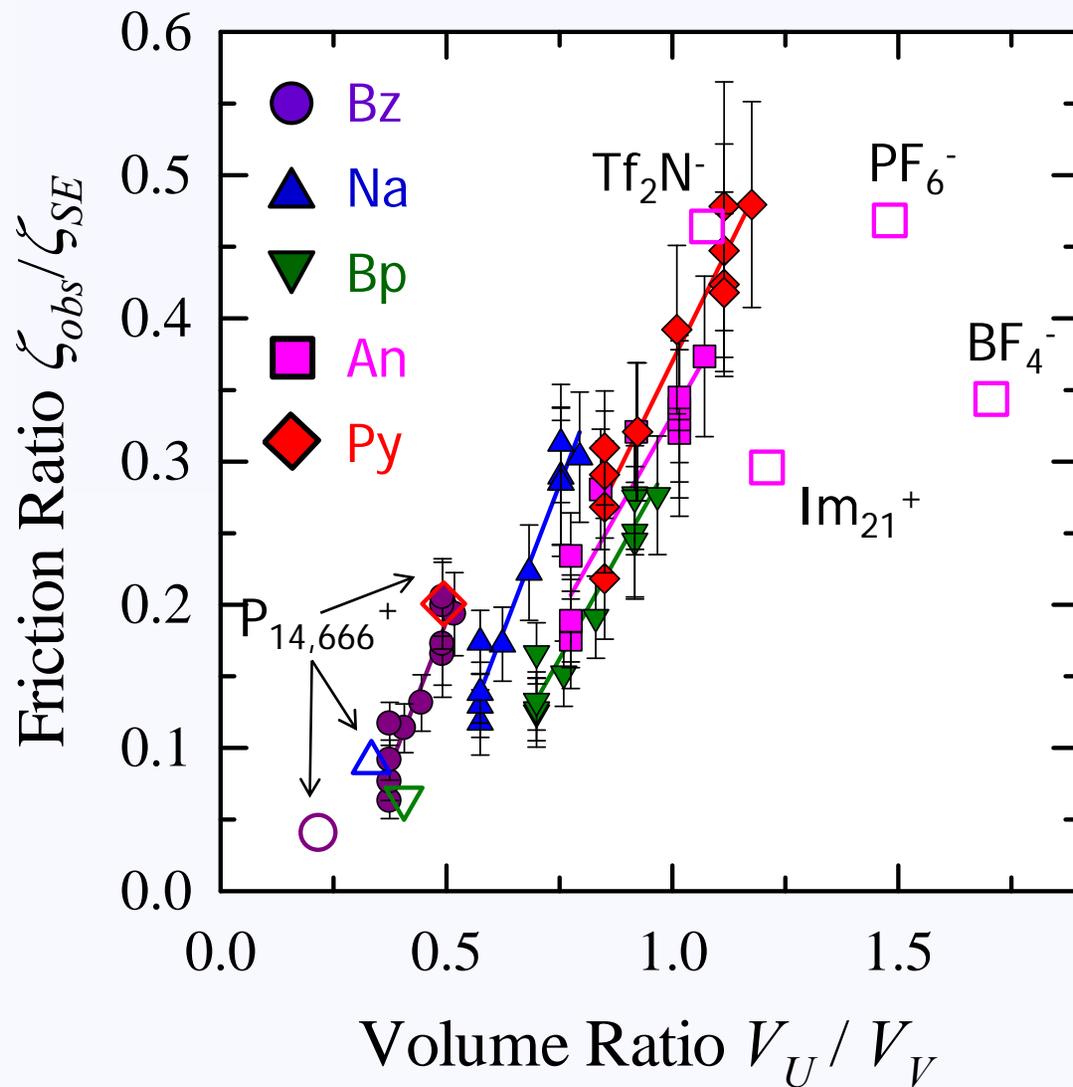

- for a single solute  $\zeta_{obs}/\zeta_{SE}$  ~ linear with solute/solvent volume ratio  $V_U/V_V$
- not a single correlation
- for fixed  $V_U/V_V$   $\zeta_{obs}/\zeta_{SE}$  possibly related to solute shape

	$\kappa$	
Bz	+1	oblate
Na	-.40	
Py	-.69	
An	-.91	
Bp	-.94	-1=prolate

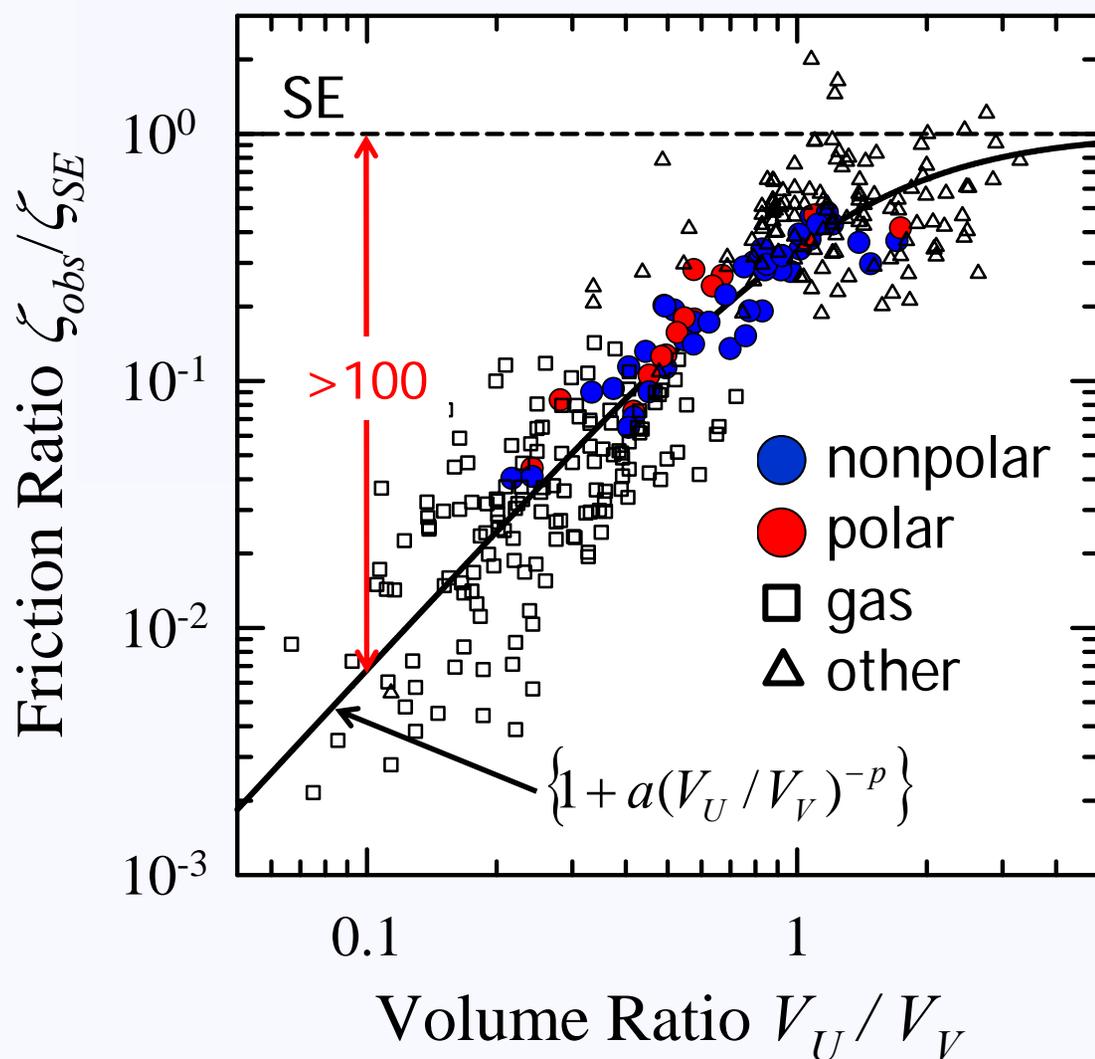

↑  $\zeta_{obs}/\zeta_{SE}$

# It's not that Simple...

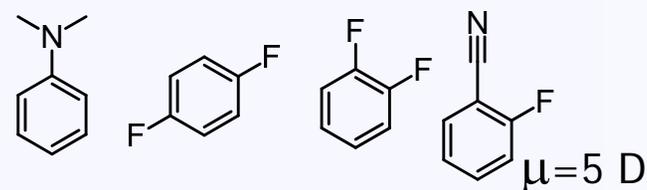

- in  $[P_{14,666}][Tf_2N]$  extends the same correlation
- $\zeta_{SE} > 50\zeta_{obs}$  for benzene in  $[P_{14,666}][Tf_2N]$
- anthracene in other ILs deviates

# Adding Polar Solutes & Literature Data

- polar solutes (this work)

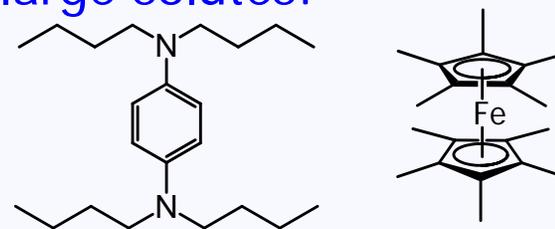

- literature data:  
323 solute/solvent pairs,  
37 solutes, 56 ILs

- small gaseous solutes:

$\text{CO}$ ,  $\text{CO}_2$ ,  $\text{C}_2\text{H}_4$ ,  $\text{C}_4\text{H}_{10}$ , ...

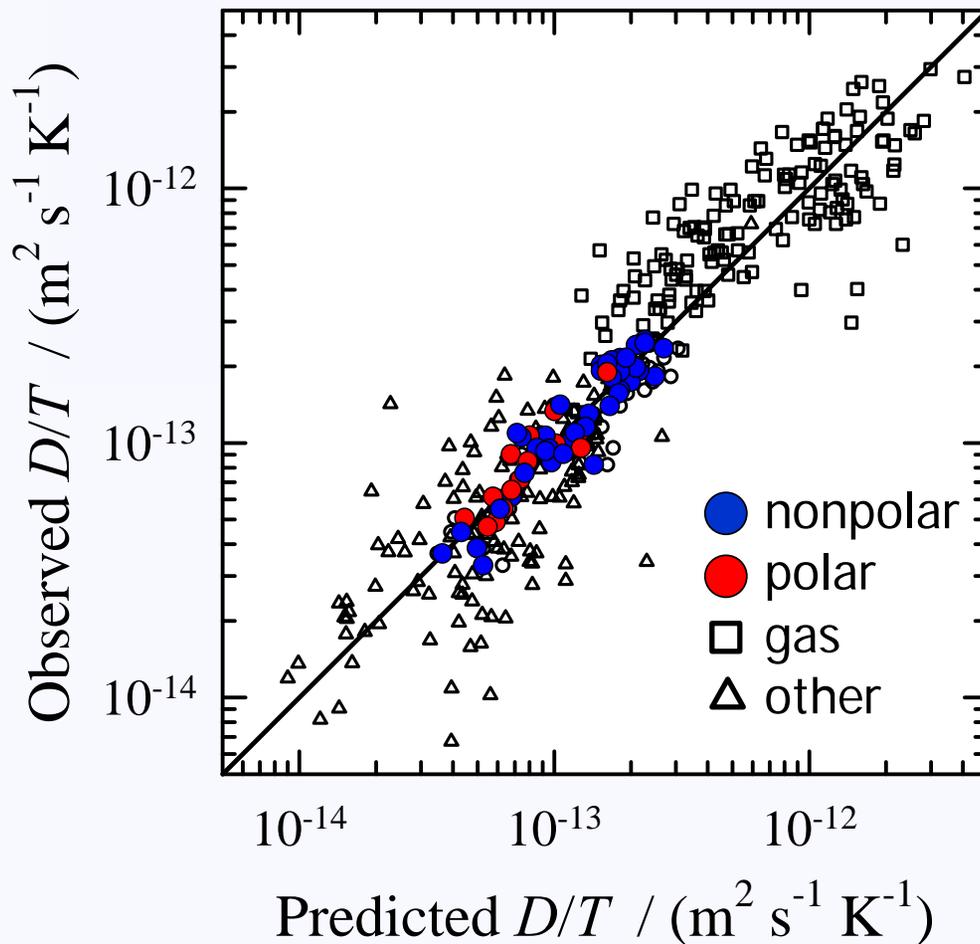

- large solutes:

lit. data from: Baltus, Scovazzo, Kimura,  
Hardacre, Compton,  
License, Halpiot, Lagroste, Hussey, ...

# No Accurate Correlations Found

## Neutral Solutes in ILs

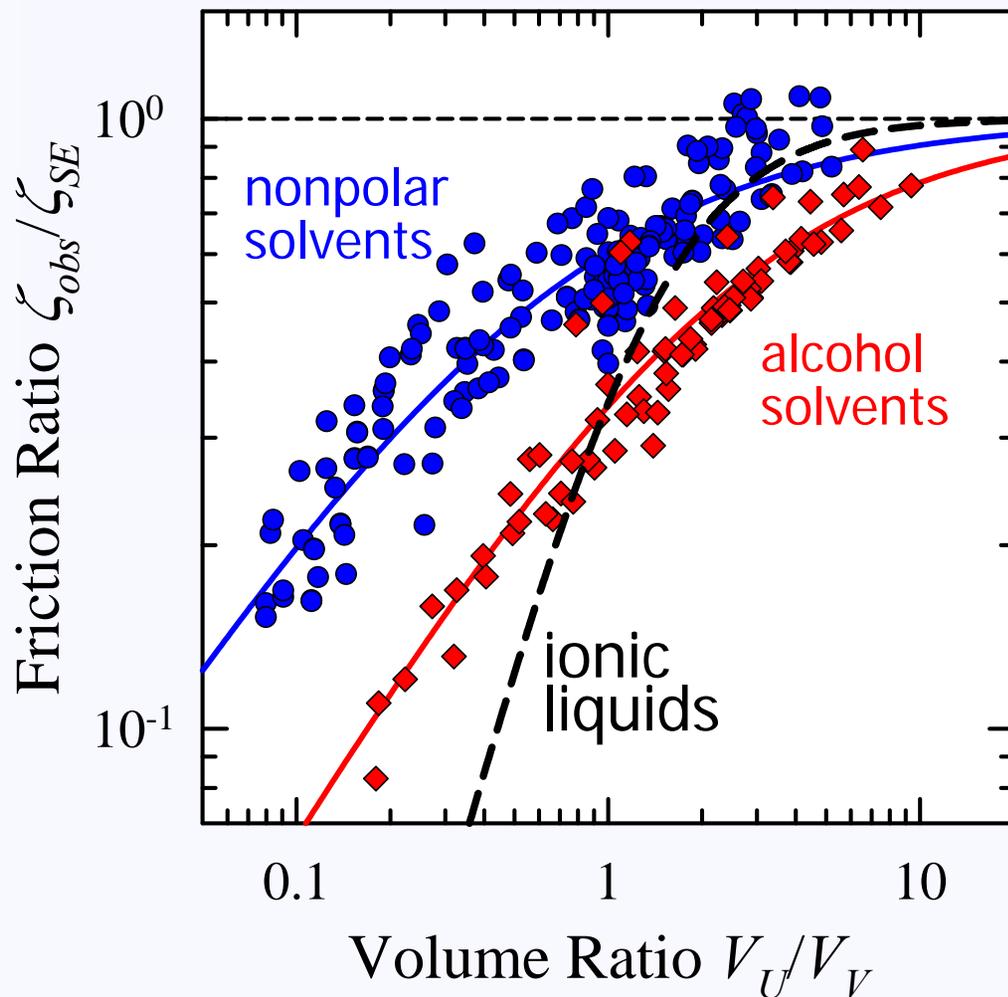

- tried to correlate  $\zeta_{\text{obs}}/\zeta_{\text{SE}}$  or  $D_{\text{obs}}$  to various solute and solvent properties
- best result (shown) was
$$\ln(D/T) = -23.14 - 1.77 \ln V_U + 0.84 \ln V_V - 0.52 \ln \eta$$

- standard error  $\pm 0.54 \leftrightarrow$   
~55% average error

➤ no more predictive than single variable correlation with  $V_U/V_V$

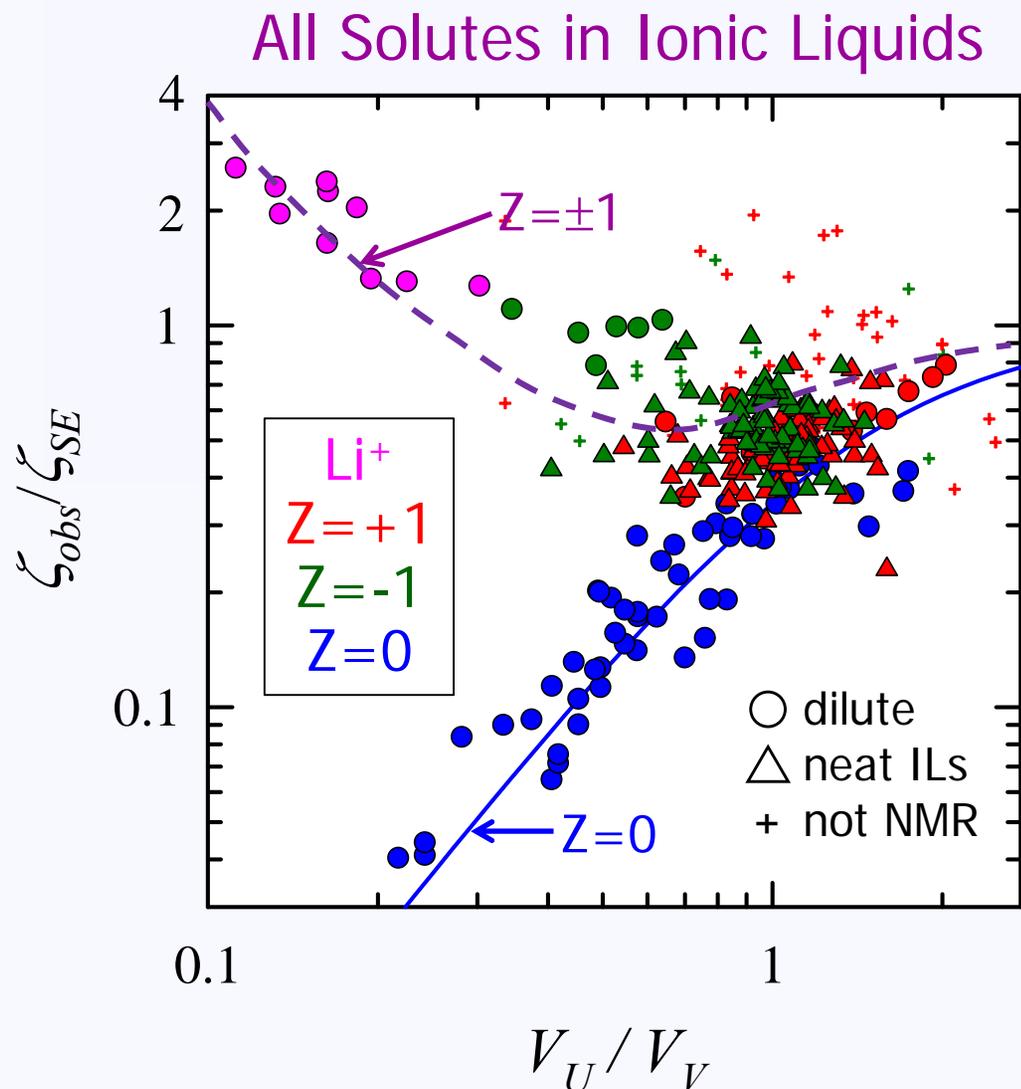

# Similar in Conventional Solvents

## Neutral Aprotic Solute Data

- $\zeta_{obs}/\zeta_{SE}$  is also primarily correlated to  $V_U/V_V$  in conventional solvents
- stronger V-V than U-V interactions lead to greater departure from SE predictions (smaller  $\zeta_{obs}/\zeta_{SE}$ )
- $V_U/V_V$  dependence much steeper in ILs

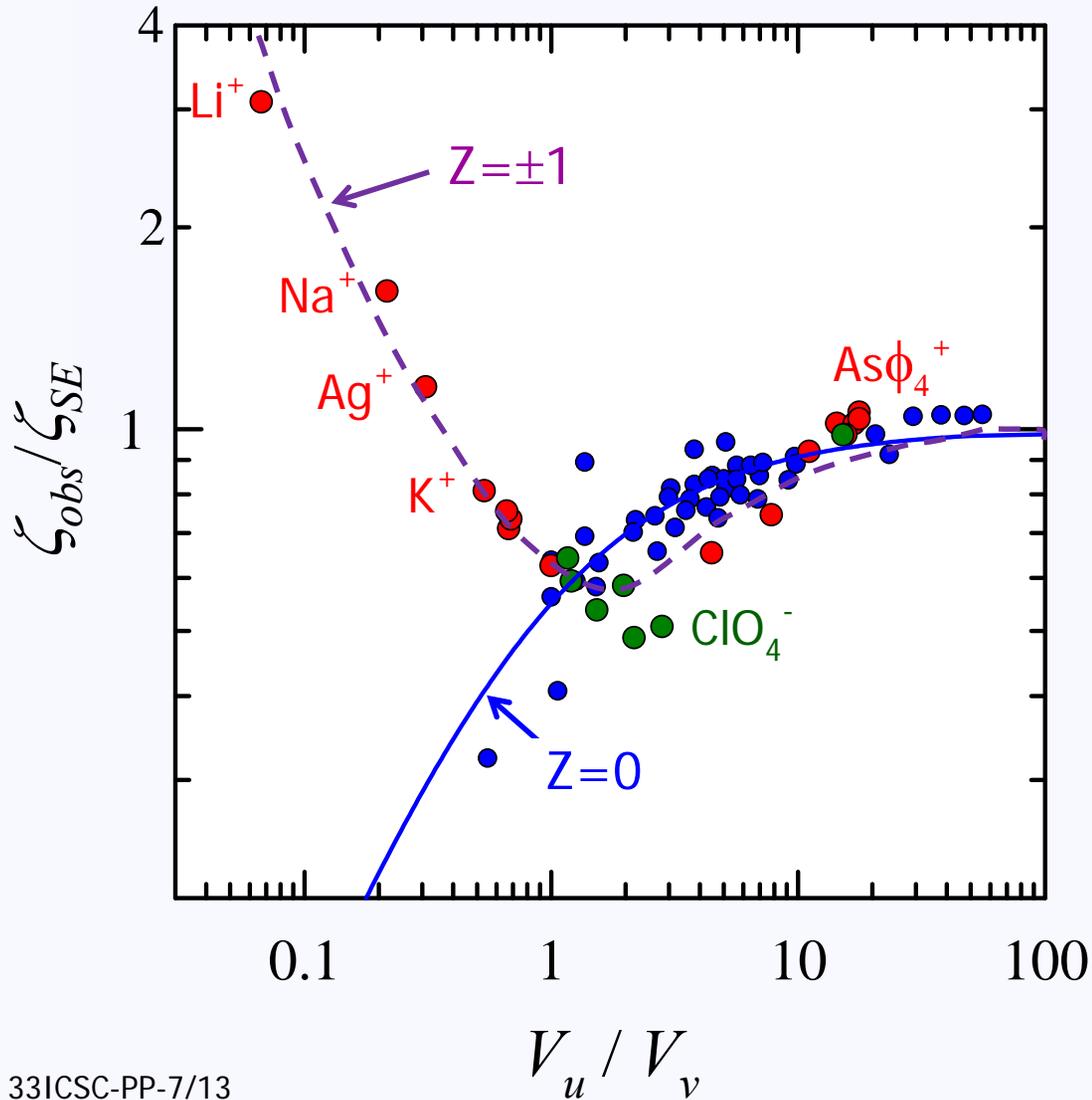

# Charged ( $Z=\pm 1$ ) Solutes in ILs

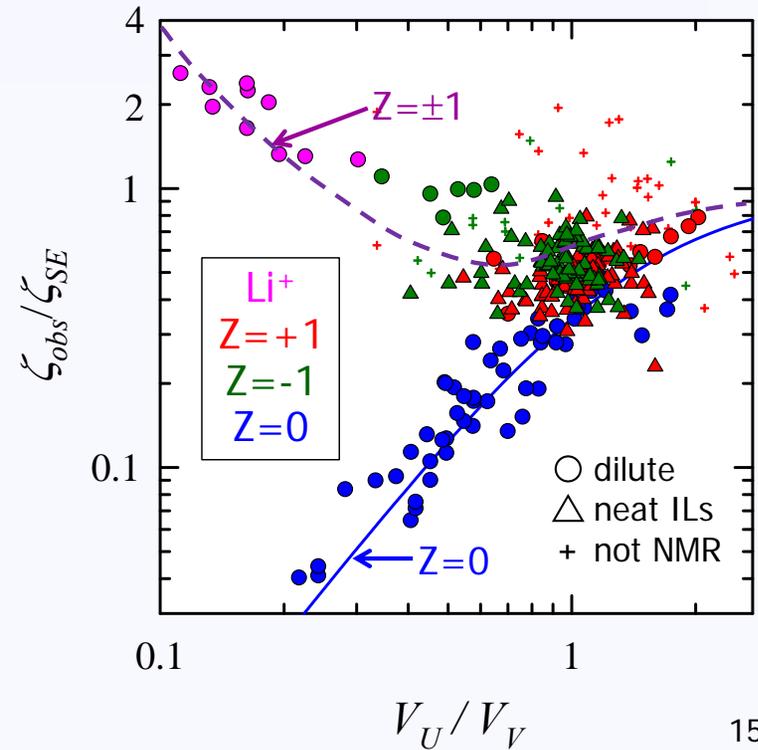

- monovalent ions show  $\zeta_{obs}/\zeta_{SE} \sim 1$  and are similar to neutrals for  $V_U/V_V \sim 1$
- for small  $V_U/V_V$   $\zeta_{obs}/\zeta_{SE}$  of charged solutes is 100× larger than that of neutrals and can exceed unity
- the “solventberg” limit well-documented for  $\text{Li}^+$  solute

# Analogous Behavior in Water

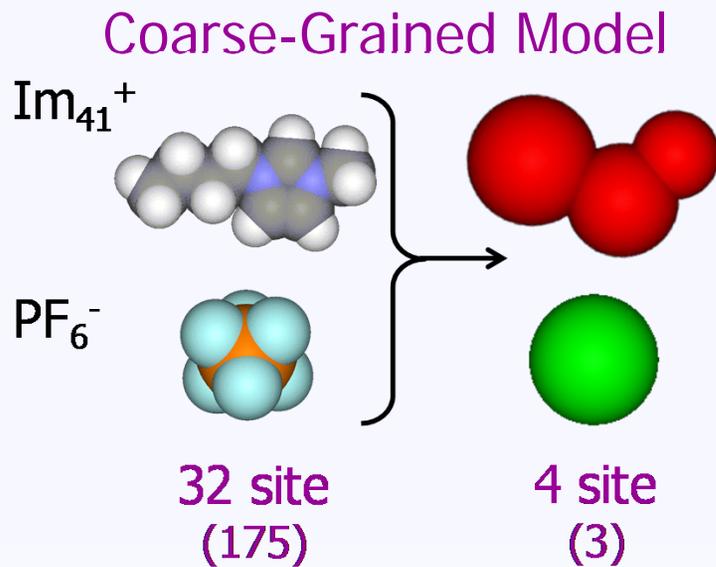

## Solute Diffusion in Water

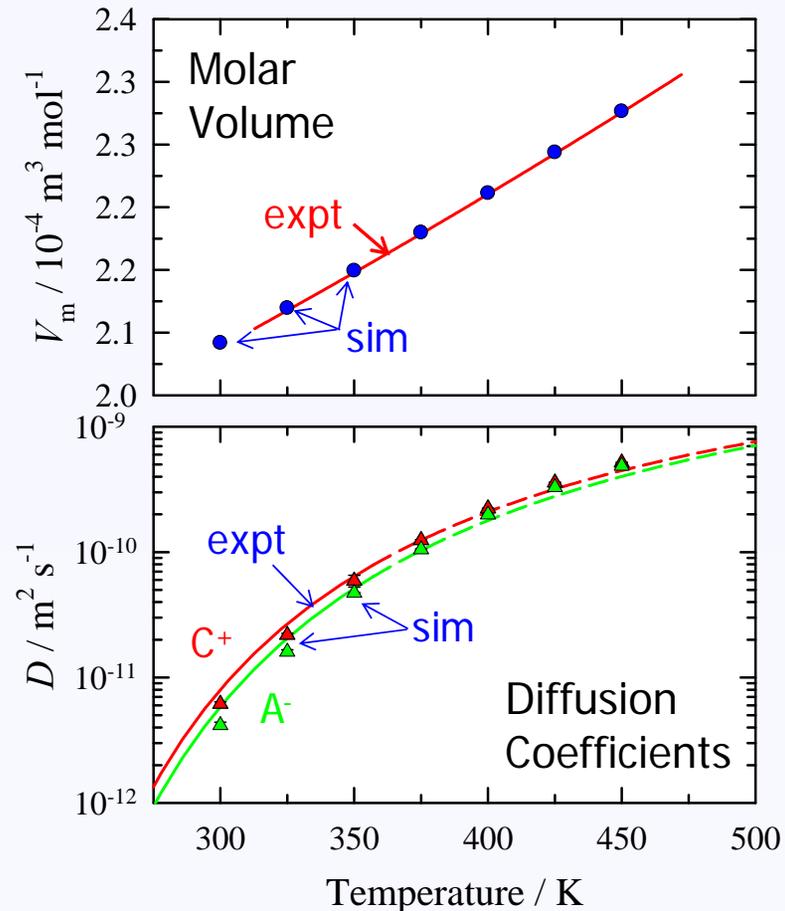

- quite similar differences are observed between neutral and monovalent solutes diffusing in water

# Insights from MD Simulations

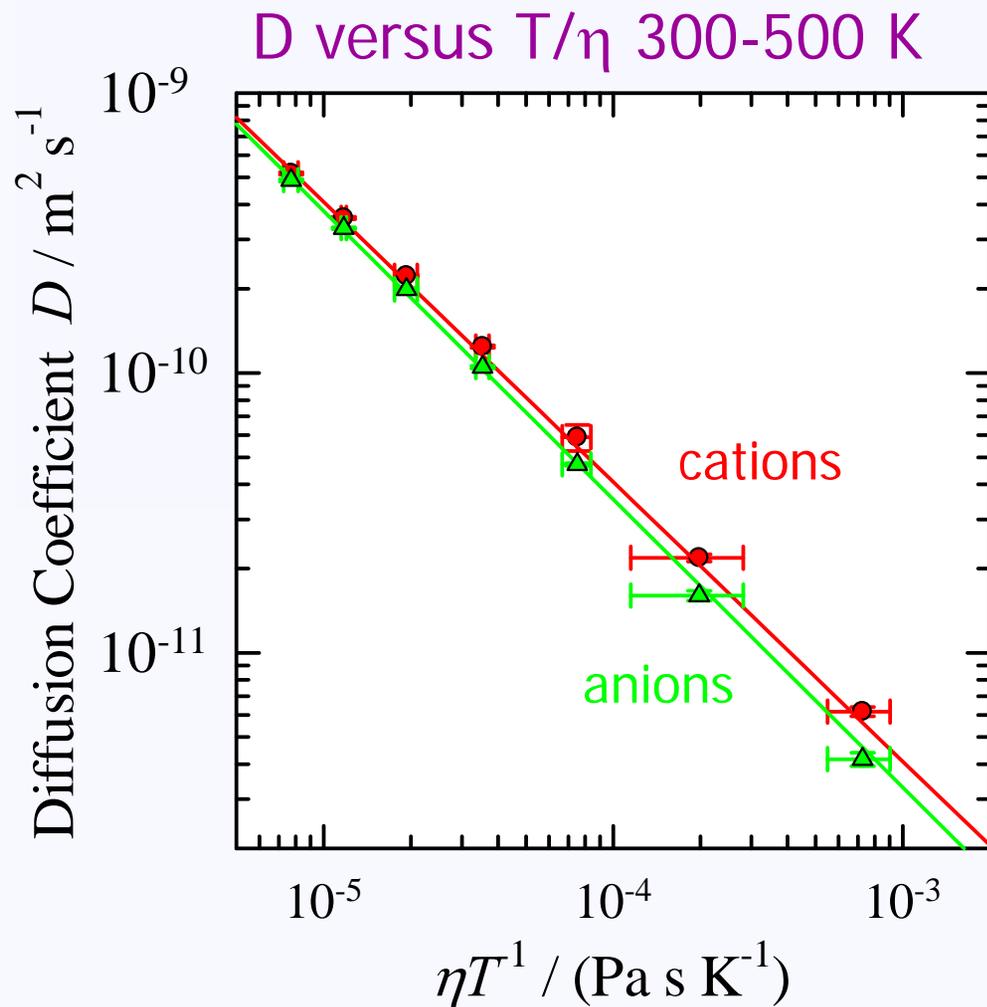

- LJ + q interactions
- group volumes & charges roughly matched to AA model
- cation geometry approximates average over  $\text{Im}_{41}^+$  conformers
- tuned to reproduce  $V_m$  &  $D_i$
- $|q| = 0.78$

- T-dep. viscosity & conductivity
- surface tension (Merlet et al.)

# Comparison to Hydrodynamics

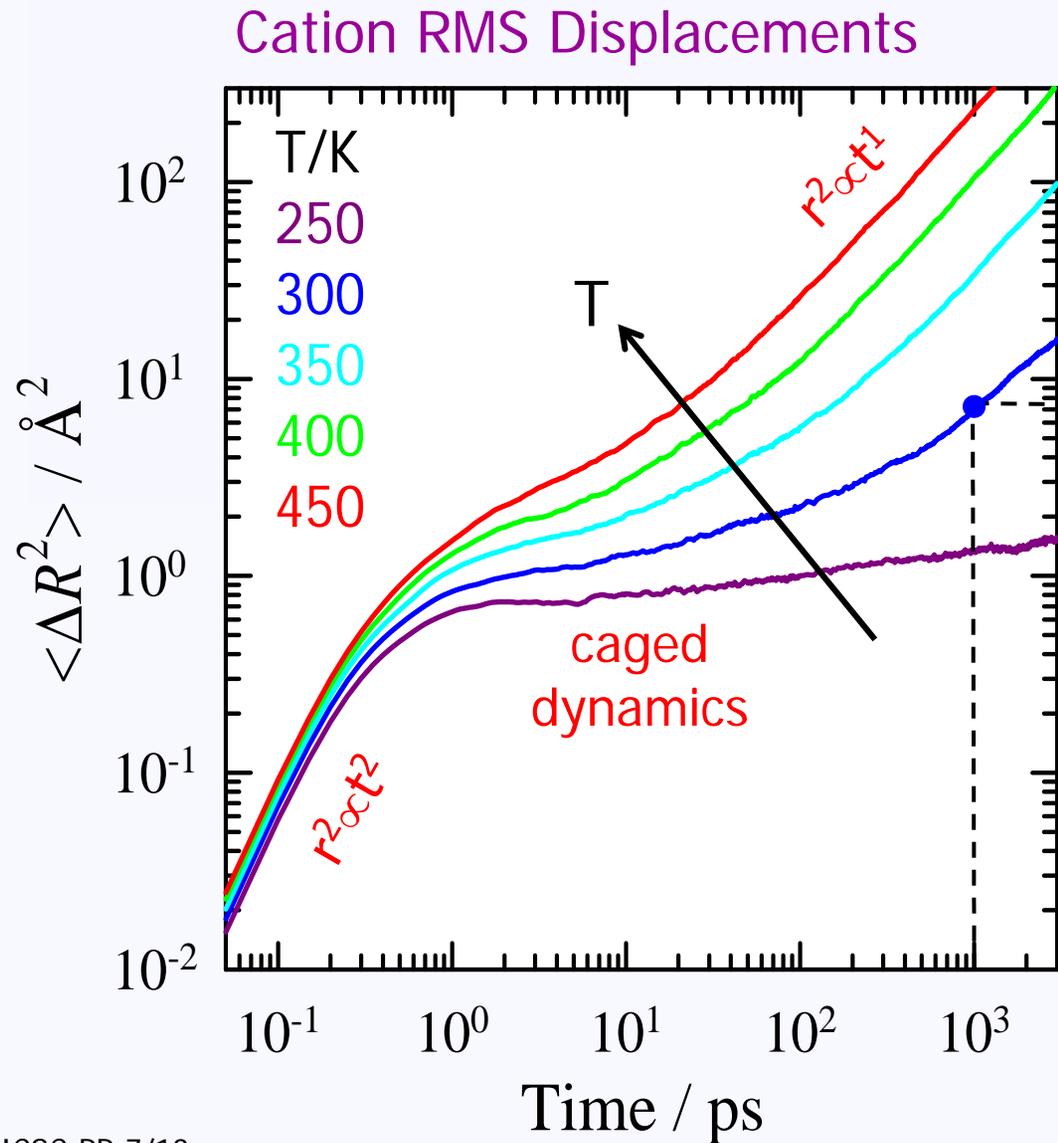

- for both cations and anions

$$\frac{D}{T} \propto \eta^{-p}$$

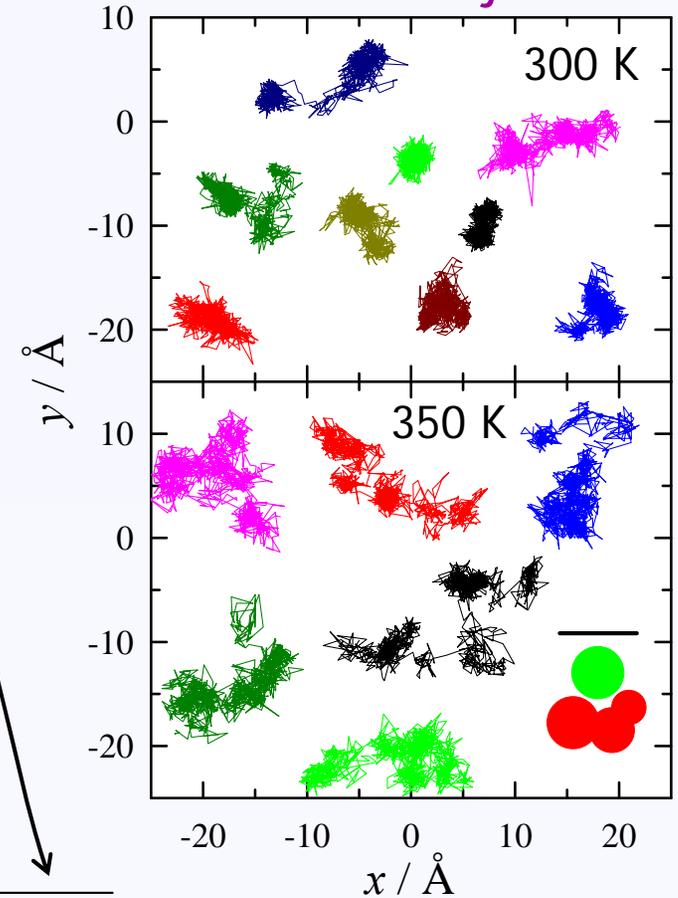

with  $p=1.0$

	$\zeta_{\text{obs}} / \zeta_{\text{SE}}$	$\zeta_{q=1} / \zeta_{q=0}$
cation	1.1	3.4
anion	1.0	2.9

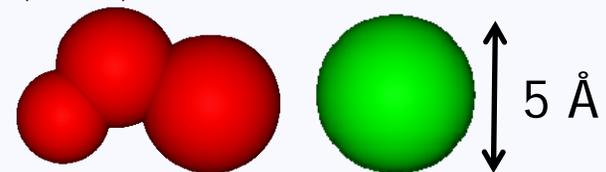

# Translational Caging

## 5 ns Cation Trajectories

$$\sqrt{\langle \Delta R^2 \rangle} = 2.5 \text{\AA}$$

# Summary & Conclusions

- ❑ the hydrodynamic Stokes-Einstein (SE) equation,  $D=k_B T/6\pi\eta R$ , provides good estimates for self-diffusion of molecules in dipolar liquids and ions in ionic liquids ( $\zeta_{\text{obs}}/\zeta_{\text{SE}} \sim 0.6 \pm 0.2$ ); in such systems the diffusing species has similar size and interactions with the “solvent” species
- ❑ neutral solutes diffusing in ionic liquids can show quite large departures from SE predictions ( $\zeta_{\text{obs}}/\zeta_{\text{SE}} < .01$ ); the primary variable controlling  $\zeta_{\text{obs}}/\zeta_{\text{SE}}$  here is the relative size of solute and solvent species,  $V_U/V_V$
- ❑ charged ( $Z=\pm 1$ ) solutes do not depart from SE predictions at low  $V_U/V_V$  like  $Z=0$  solutes; for sufficiently small ions  $\zeta_{\text{obs}}/\zeta_{\text{SE}} > 1$  due to “solventberg” formation
- ❑ parallel behavior is observed for  $Z=0, \pm 1$  solute diffusion in ionic liquids and in conventional solvents
- ❑ simple and predictive models not available for either solvent class
